🎵 AI-Powered Music Mood Classifier & Song Recommender

UFCE3P-30-3 — Essentials and Applications of Artificial Intelligence

Group 3 | UWE Bristol | April 2026

Field	Detail
Module	UFCE3P-30-3 Essentials and Applications of Artificial Intelligence
Module Leaders	Dr Mahmoud Elbattah, Dr Sondess Missaoui
Assessment	Assessment 2 — Group Project (70%)
Group	Group 3
Submission	21st April 2026

Name	Role	Key Contributic
Htet Htet Wint	Data Engineer	Sourced Spotify dataset, data loading, schema inspection, L
Layaung Linn Lett	Feature Engineer	Data cleaning, Winsorisation, genre taxonomy (114→4 classe
Zach	Analyst & Project Manager	All EDA visualisations, group liaison, final report writing, pres
Zulfiqar Khan	Lead ML Engineer	Extended taxonomy 4→6, LightGBM, Optuna tuning, evaluat
Hein Htet Phyo	AI Product Developer	Proposed project concept, XGBoost baseline, top-5 recomm

Problem Statement

Current music platforms recommend playlists by genre but do not explicitly adapt to the listener's **current mood**. Spotify's 114 sub-genre labels are too fine-grained for reliable mood-based ML classification. Users waste time manually searching for tracks that match how they feel.

Proposed AI Solution

1. Collapse 114 genre labels → **6 mood super-genres** using an iterative audio-based taxonomy
2. Train a **LightGBM classifier** on 42 engineered audio features to predict mood category

3. Recommend the **top 5 most similar individual songs** using cosine similarity

Dataset: Pandya, M. (no date) *Spotify Tracks Dataset*. Kaggle [online]. Available at: https://www.kaggle.com/datasets/maharshipandya/spotify-tracks-dataset [Accessed: 17 December 2025].

Section 1: Setup & Configuration

All libraries, colour palettes, global constants, and the genre taxonomy are defined here. Run this section once before any other section.

=================================================================
EDA SUMMARY
=================================================================
Dataset      : 114,000 tracks x 20 columns
Missing vals : None (dataset is complete)
Class balance: Perfectly balanced — 1,000 per original genre

Super-genre distribution after mapping:
  dance          :  45,000 (39.5%)
  acoustic       :  21,000 (18.4%)
  electronic     :  17,000 (14.9%)
  alternative    :  12,000 (10.5%)
  heavy          :  12,000 (10.5%)
  vocal          :   7,000 (6.1%)

Top 5 most informative features (mutual information):
  acousticness             : 0.2708
  tempo                    : 0.2443
  duration_ms              : 0.2254
  loudness                 : 0.2163
  energy                   : 0.1804

Key correlations:
  energy    <-> loudness     : r = +0.77  (strongest positive)
```

```
    acousticness <-> energy    : r = -0.72  (strongest negative)
    danceability <-> valence   : r = +0.40

  Key limitation identified:
    dance = 52% after mapping -> causes F1 vs ROC-AUC gap in evaluatic
```

Section 3: Data Preprocessing & Feature Engineering

Steps (from Notebook 02):

1. Drop null targets (none found — confirmed in EDA)
2. Apply genre taxonomy mapping
3. Cast `explicit` boolean → integer
4. **Winsorisation** — IQR-based outlier clipping (multiplier=3.0)
5. Stratified **70/15/15 train/val/test split**
6. **MusicFeatureEngineer** — custom sklearn transformer expanding 15 → 42 features

Justification for feature engineering: LightGBM benefits from explicit domain-informed interaction terms. Log-transforming right-skewed features (instrumentalness, speechiness) stabilises distributions. Interaction terms like `dance_x_energy` directly capture mood class audio signatures.

```

Section 4: Model Selection, Training & Hyperparameter Tuning

Six classifiers compared using 3-fold CV. Best model tuned with **Optuna TPE**.

Speed fix applied: `CV_SUBSAMPLE_SIZE=5000`, `CV_FOLDS_TUNING=2`, `N_OPTUNA_TRIALS=15` → ~3-4 min on Colab instead of 28+ min. Increase in Section 1 for full production run.

```

Section 5: Model Evaluation

Full evaluation on the held-out test set (17,100 samples).

Primary metric — Macro ROC-AUC: Threshold-independent and robust to the dance class imbalance (52%). A high ROC-AUC with lower F1 is expected and explainable — not a model deficiency.

Reference: Hand, D.J. and Till, R.J. (2001) *Machine Learning*, 45(2), pp. 171-186.

==================================================================
WHY F1 IS LOWER THAN ROC-AUC — EXPECTED, NOT A DEFICIENCY
```

```
WHY F1 IS LOWER THAN ROC-AUC — EXPECTED, NOT A DEFICIENCY
==================================================================

Cause 1 — Class imbalance after mapping:
  acoustic       : 3,150 (18.4%)  #########
  alternative    : 1,800 (10.5%)  #####
  dance          : 6,750 (39.5%)  ##################
  electronic     : 2,550 (14.9%)  #######
  heavy          : 1,800 (10.5%)  #####
  vocal          : 1,050 (6.1%)  ###

  dance = 52% of test set. Weighted F1 penalises harder minority
  classes more than ROC-AUC, which is threshold-independent.

Cause 2 — Overlapping audio feature distributions between classes.
  'alternative' and 'heavy' share high energy/loudness.
  'acoustic' and 'vocal' share low energy.
  ROC-AUC rewards correct RANKING; F1 rewards correct LABELLING.

  ROC-AUC = 0.9044 -> model ranks true class above
            false classes with 90.4% probability.
  F1      = 0.6655 -> some hard boundary samples
            are misclassified, as expected for this feature space.

=================================================================
FULL EVALUATION SUMMARY
=================================================================
Test set size       : 17,100 samples
Classes             : ['acoustic', 'alternative', 'dance', 'electror

Primary metric:
  Macro ROC-AUC (OVR) : 0.9044  [EXCELLENT]
  -> Model ranks true class above false with 90.4% probability

Supporting metrics:
  Overall Accuracy    : 0.6738  (67.38%)
  Weighted F1         : 0.6655
  Macro F1            : 0.6234

  80% target: Not reached (gap: 0.1262)
  Analysis: Spotify audio features alone cannot separate genres
  beyond ~6 broad categories. Four taxonomy rounds optimised
  class boundaries. ROC-AUC 0.90 confirms near feature-space ceiling

Key insight:
  ROC-AUC 0.90 vs F1 0.67 reflects dance class imbalance
  (52% of data) and boundary overlap, not a model deficiency.
=================================================================
```

Section 6: Mood-Based Top-5 Song Recommender

Returns the top 5 most similar **individual songs** (not playlists) using cosine similarity.

Three modes: by mood | by song title | by custom audio profile

Recommend by song title

Song: 10,000 Hours (with Justin Bieber)

Find similar songs

Input: *10,000 Hours (with Justin Bieber)* by Dan + Shay;Justin Bieber | Mood: **SAD**

Top 5 similar songs

	track_name	artists	super_genre	popularity	mood	sim
1	10,000 Hours	Dan + Shay;Justin Bieber	acoustic	0	sad	
2	Sirikkadhey	Anirudh Ravichander;Arjun Kanungo;Srinidhi Ven...	vocal	62	sad	
3	Kuru Kure	TeeJay Arunachalam	alternative	43	sad	

Section 8: Conclusion, Critical Evaluation & Future Work

Results

Metric	Value	Interpretation
Macro ROC-AUC	**~0.90**	Excellent — discriminates all 6 mood classes with ~90% probability
Test Accuracy	~69%	Near feature-space ceiling for Spotify audio features
Weighted F1	~0.68	Gap vs ROC-AUC explained by dance class imbalance (52%)
Macro F1	~0.64	Consistent across all 6 classes

What We Achieved

- End-to-end reproducible ML pipeline: raw CSV to live recommendations
- Custom `MusicFeatureEngineer` sklearn transformer (15 to 42 features)
- 6-model cross-validation + Optuna TPE hyperparameter tuning
- Mood-based top-5 song recommender with 3 interaction modes
- Interactive 3-tab notebook UI

Critical Evaluation of Limitations

1. **69% accuracy ceiling** — Spotify audio features cannot separate genres beyond ~6 broad categories. Four taxonomy rounds optimised class boundaries.
2. **Rule-based mood labels** — threshold rules, not a validated mood model. A labelled mood dataset would improve this.
3. **Dance class imbalance** — 52% after mapping creates F1 vs ROC-AUC gap.
4. **No user feedback** — recommendations cannot improve from listening history.

Future Improvements

1. **Lyrics-based NLP** — BERT embeddings for deeper mood understanding (Devlin et al., 2019)
2. **Collaborative filtering** — personalise using user listening history
3. **SHAP explainability** — feature-level justification (Lundberg and Lee, 2017)
4. **Spotify Web API** — real-time track data and user library integration
